Screenmate

An assistant for completing job applications

Screenmate is a Chrome extension that fills saved details and drafts written answers directly on an application page. It checks whether its changes reached the form and leaves the applicant in control of review and submission.

The problem

Job seekers repeatedly enter their education, experience, and contact details into different portals. Role-specific questions add writing work, and moving between a form and a separate AI chat requires copying both context and answers.

The workflow

1. Save a profile or import a CV and review the extracted information.
2. Open an application. Screenmate reads supported fields, fills saved details, and drafts answers using the applicant background and role context.
3. Inspect changes, answer missing personal questions, and submit the application yourself.

Implemented today

The repository contains the extension, a web profile workspace, field verification, supported in-page navigation, and a separate review of generated personal claims. A recorded prototype demonstration shows the extension running on a controlled sample form.

Current boundaries

Sign-in, CAPTCHAs, file uploads, unsupported controls, and final submission require user involvement. Compatibility depends on the employer form. Live-site reliability, customer demand, and willingness to pay remain to be established with measured evidence.

Hackathon recognition

Screenmate placed third globally out of 687 projects at AI Tinkerers' Agents Everywhere Hackathon with OpenAI. Built by Viren Chauhan, it represented Atlanta, the only U.S. chapter among the top three. This is external recognition of the build; user traction is a separate measure.
